Git Bash guide

1 Get the repository into your current folder

Open Git Bash in an empty folder, then run:

git clone https://github.com/Dingglebell/is403-maritime-port-forecasting.git .

The final dot means “use this folder.” Run this only once. If you already have the repository, skip this step.

2 Start your work

Inside the repository, start a new branch from main:

git switch main
git pull --ff-only origin main
git switch -c task1-han

Replace task1-han with your own new branch name. Then edit and save your files.

3 Commit and push your work

git add -A
git status
git commit -m "Update the data preparation task"
git push -u origin task1-han

Replace the message and branch with yours. git add -A stages all new, modified and deleted files across the repository, except ignored files. Check git status before committing. A commit saves locally; push uploads to GitHub.

4 Create a pull request

Open the repository on GitHub. Click Compare & pull request, set the base to main and compare to your branch, add a title and short description, then click Create pull request. If the banner is absent, use Pull requests → New pull request. Ask a teammate to review before merging.

After the pull request is merged, with your work committed:

git switch main
git pull --ff-only origin main

Start the next task on a new branch.

5 Save all changes directly to main

If you are already on main and want to publish without a pull request:

git add -A
git status
git commit -m "Update project files and rename manifest"
git push origin main

For the rename from data/manifest.example.csv to data/example.csv, first replace !data/manifest.example.csv with !data/example.csv in .gitignore. Otherwise, the new filename stays ignored. Then run the commands above; they include the rename and the .gitignore change.
